1.1 Introduction

Throughout the millennia humans have developed and adapted methods for storing facts and thoughts on a variety of different mediums. A very efficient way of doing this is using logograms, like Chinese have done for ages. Another method is to represent each syllable in a word by a symbol, like the Japanese do when writing telegrams. However, the most common way of storing characters is by using a limited set of shapes representing basic sounds (a.k.a. phonemes). Such a collection is called an *alphabet*, and the shapes are called *letters*.

TEX is primarily meant for typesetting languages that use this third method. The other two methods can also be dealt with, but some extra effort is needed. In this chapter we will focus on languages that use alphabets, the other methods will be explained in later chapters.

The shapes representing the characters that make up an alphabet are more or less standardized, and thereby can be recognized by readers even if their details differ. A collection of pictures matching character shapes is called a *font*, and the pictures in a font are called *glyphs*.

gap gap gap gap

From left to right you see a Computer Modern font, a Helvetica lookalike, a Times Roman lookalike and the Antiqua Torunska font, all scaled to 60pt. As you can see, quite some variation is possible and when intermixed, the result is not always pleasing to look at. The term *fonts collection* refers to a set of fonts combined together in such a way that the overall appearance on a page looks good and reading is as comfortable as possible.

lap lap lap lap

Even within a single font design there can be variations. In the example above there are a light, a bold, an italic, and a bold italic *alternative* of a single font. Such a set of fonts with the same basic design is known as a *font family*.

The distance between the individual glyphs in a word and the actual glyphs that are used depends on the combinations of these glyphs. In the top line of the next sample, the gap between the b and the o as well as the distance between the o and the x is slightly altered. This is called kerning. Further, the separate glyphs for the f and the i have been combined into a single one. This is called ligaturing.

Introduction 1

The font shown here is Computer Modern, the default TeX font. This font is designed by Donald Knuth. The Computer Modern has many kerning pairs, while the Palatino–like font that is used for most of the text in this manual has only a few, while both have essentially the same list of ligatures.

Micro-typography like kerning pairs and ligatures are not to be altered by the user, they are part of the font design and the required data is stored inside the font file, together with the drawing routines for the actual pictures. It *is* possible for the user to alter fonts and interline spacing and some more aspects on the level of macro-typography. The choice of font is the main topic of this chapter.

There are many different methods that can be used to classify fonts. There are classification systems based on the period in which the style was first developed; on the characteristics of the font; or the font application, like a newspaper or a book. Often, classification systems mix these characteristics up to some point.

For example, the Computer Modern family can be classified as a 'modern' font. This is a classication that primarily indicates a period (late 18th century), but it also implies a particular shape: 'modern' fonts have a high contrast between thick and thin strokes, and their stress axis is perfectly vertical.

At the same time, specific fonts in the Computer Modern family can be classified as 'serif' (glyphs strokes have embellishments at the end), 'sans serif' (shapes end abruptly), or 'monospaced' (all glyphs have the same width).

The Computer Modern family is in fact inspired by one font in particular: 'Modern 8a' by the Monotype corporation. Knuth implemented Computer Modern in METAFONT using parameters so that he could generate a whole collection of fonts all closely matching eachother in style. In ConTeXt you will normally use a reimplementation of Computer Modern using a more modern file format (Type 1 or OpenType). This new version is called 'Latin Modern', and also features an extended glyph set making it usable for languages that could not be typeset with Knuth's original fonts.

ok ok ok ok

In this example you see five font styles of Latin Modern: the Roman, Sans, Typewriter, Smallcaps and Variable Typewriter. Computer Modern is one of the few font families that comes with dedicated design sizes. The example below shows the differences of a 5, 7, 9, 12 and 17 point design scaled up to 48 points. Such nuances in font size are seldom seen these days.

1 Introduction

ok ok ok ok

As explained earlier, the general appearance of a font style can be classified according to many schemes. In table 1.1 you can see some examples of the naming of font styles that are often found together in a single document.

Serif Sans Mono Regular Support TeleType Roman Sans Type

Table 1.1 Some ways of classifying the styles in a font.

The top two series are normally used by typographers, the bottom series is what was traditionally used in plain TeX. In ConTeXt all three series of terms can be used because they are remapped to the same set of internal commands. As will be explained later, the command \rm is used to switch to a roman/serif/regular style, and \tt for switching to mono spaced or typewriter style, etcetera.

Text can be typeset in different font sizes. The unit pt is often used to specify the size. The availability of these font sizes are defined in definition files. Traditionally font designers used to design a glyph collection for each font size, but nowadays most fonts have a single design size of 10 points, or small set of sizes with names indicating their proposed use, like *caption*, *text*, and *display*.

The next sections will go into the details of switching of font styles and fonts in your documents. Be warned that the font switching mechanism is rather complex. This is caused by the different modes like math mode and text mode in ConTeXt. If you want to be understand the mechanism fully, you will have to acquaint yourself with the concept of encoding vectors and obtain some knowledge on fonts and their peculiarities.

1.2 The mechanism

Font switching is one of the eldest features of ConTeXt because font switching is indispensable in a macro package. During the years extensions to the font switching mechanism were inevitable. The following starting points have been chosesn during the development of this mechanism:

- To change a *style* must be easy, this means switching to: roman (serif, regular), sans serif (support), teletype (monospaced) etc. (\rm, \ss, \tt etc.)
- More than one *alternative* set of glyphs shapes must be available like slanted and bold (\sl and \bf).
- Different font *families* like Latin Modern Roman and Lucida Bright must be supported.
- It must be possible to combine different families into font *collections*.

The mechanism 1

- Different sub— and superscripts must be available. These script sizes have to be retained across the switching of family, style and alternative.
- It should be possible to combine all of these requirements into a single definition unit called a *body font*.
- Changing the global font collection as well as the size must also be easy, and so sizes between 8pt and 14.4pt must be available by default.

Before reading further, please stop for a moment to make sure you thoroughly comprehend the above paragraphs. ConTeXt's terminology probably differs from what you are accustomed to, especially if you were previously a LaTeX user.

1.3 Font switching

The mechanism to switch from one style to another is somewhat complex, not in the least because the terminology is a bit fuzzy. A quick recap: we call a collection of fonts, like Lucida or Computer Modern Roman, a *family*. Within such a family, the members can be grouped according to characteristics. Such a group is called a *style*. Examples of styles within a family are: 'roman', 'sans serif' and 'teletype'. We saw already that there can be alternative classifications, but they all refer to the presence of serifs and the glyphs having equal widths. Within a style there can be *alternatives*, like 'boldface' and 'slanted'.

There are different ways to change into a new a style or alternative. You can use \ss to switch to a sans serif font style and \bf to get a bold alternative. When a different style is chosen, the alternatives adapt themselves to this style. Often a document will be typeset using just one combination of family and style. This is called the bodyfont.

Consistent use of commands like \bf and \sl in the text will automatically result in the desired bold and slanted altermatives when you change the family or style in the setup area of your input file.

1.3.1 Font style switching

Switching to another font style is done by one of five two-letter commands that are listed in table 1.2.

```
\rm serif, regular, roman, rm
\ss sans, support, sansserif, ss
\tt mono, type, teletype, tt
\hw handwritten, hw
\cg calligraphic, cg
_ mm
```

Table 1.2 Font style switching commands

The 'handwritten' and 'calligraphic' font styles are sometimes useful when dealing with very elaborate document layout definitions. In the ConTeXt distribution, only the Lucida font family uses these styles, in any other font set they are simply ignored. You could use them in your own font setups if you so desire (see the next chapter for font setup definitions).

There is a sixth internal style that is only ever referenced as 'mm'. This style handles math fonts. It does not make sense to use this style directly so there is no command attached to it, but it is quite important internally so it makes sense to introduce it right away.

1.3.2 Font alternative switching

The alternatives within a style are given in table 1.3. Not all fonts have both italic and slanted or the bold alternatives of each. Some other fonts do not have small caps or only one set of digits. When an alternative is not known, ConTeXt will attempt to choose a suitable replacement automatically. For instance, the italic alternative may be used for if slanted is not available or vice versa.

```
\bf
       bold
       slanted
\sl
\it
       italic
       boldslanted, slantedbold
\bs
\bi
       bolditalic, italicbold
\sc
       smallcaps
       mediaeval (from oldstyle)
\os
       normal (from typeface)
\tf
```

Table 1.3 Font alternative switching commands and their keyword equivalents. With \os you tell ConTEXT that you prefer mediaeval or old-style numbers as in 139 over 139.

Besides these two-letter commands, there is a series of font selector commands with a suffix attached. Some examples of that are:

```
\tfx \bfx \slx \itx
\tfa \tfb \tfc \tfd \tfxx
```

Each of the ordered alphabetic suffixes a, b, \dots select a somewhat larger actual font than the previous one. The x and xx suffixes select smaller and yet smaller versions.

```
\bfx smallbold
\slx smallslanted
\itx smallitalic
\bsx smallboldslanted, smallslantedbold
\bix smallbolditalic, smallitalicbold
\tfx small, smallnormal
```

Table 1.4 Small alternative switching commands and their keyword equivalents.

Besides the 'small' switches that are mentioned in table 1.4, it depends on the completeness of the font definition files whether commands like \ita, \bfxx, \bfc, etc. are available. For the core ConTeXt fonts, you can count on at least \tfa, \tfb, \tfc, \tfd, and \tfxx being defined. For the others, just try and see what happens.

When you have chosen a larger charactersize, for example \tfb, then \tf equals \tfb, \bf equals \bfb, etc. This method is almost always preferable over returning to the original character size, but it may catch you off-guard.

More generic font scaling commands are also available:

```
\tx \txx
```

\setsmallbodyfont \setbigbodyfont

The command \tx adapts itself to both the style and the alternative. This command is rather handy when one wants to write macros that act like a chameleon. Going one more step smaller, is possible too: \txx. Using \tx when \tx is already given, is equivalent to \txx.

The commands \setsmallbodyfont and \setbigbodyfont switch to the 'small' and 'big' body font sizes. These relative sizes are defined via the 'body font environment', see section 1.7.4.

The various commands will adapt themselves to the actual setup of font and size. For example:

```
{\rm test {\sl test} {\bf test}} {\ss test {\sl test} {\bf test}} {\ss test {\sl test \tx test}}
```

will result in:

test test test test test test

test test test test test

When the \rm style is active, ConTEXT will interpret the command \tfd as if it was \rmd, when the style \ss is active, \tfd as is treated as \ssd. All default font setups use tf-setups so they will automatically adapt to the current font style.

The remainder of this paragraph is for completeness' sake only. Use of the following commands in new documents is discouraged.

Frequent font switching leads to longer processing times. When no sub- or superscripts are used and you are very certain what font you want to use, you can perform fast font switches with: \rmsl, \ssbf, \tttf, etc.

The plain T_EX compatible font switches $\forall i$, $\forall ii$, $\forall ii$, $\forall ix$, $\forall x$, and $\forall xii$ are also defined, these have local effects like $\forall tfx$ and $\forall tfa$.

1.3.3 Switching font styles in setup commands

A number of ConTeXt commands use the parameter style to set the used font. The parameter mechanism is rather flexible so that within the parameter style you can use any of the font switching commands like or bf or \switchtobodyfont, but also a number of keywords like

```
normal bold slanted boldslanted italic bolditalic type small smallbold smallslanted ... smallitalic ... smalltype capital
```

Most of these keywords have alread been listed in the tables 1.3 and 1.4, but a few predefined ones are still missing. These are displayed in table 1.5, together with the commands they execute. As is normal in ConTeXt, you can extend the list of accepted keywords by defining your own. This will be explained in section ?? in the next chapter.

| \tt | type, mono |
|-------------------|-----------------|
| \ttx | smalltype |
| \ss | sans, sansserif |
| \ss \bf | sansbold |
| \setsmallbodyfont | smallbodyfont |
| \setbigbodyfont | bigbodyfont |
| \smallcapped | cap, capital |
| \WORD | WORD |

Table 1.5 Remaining font alternative keywords.

1.4 Line spacing

In TEX linespacing is determined by a number of variable dimensions like \topskip, \parskip and \baselineskip. However, in ConTEXT these variables are related to the bodyfont size.

A line has a height and a depth. The distance between two lines is normally equal to the sum of the maximum height and maximum depth:

This sum is in ConTeXt equal to 2.8ex, so almost three times the height of an x. This is about $1.2\times$ the bodyfont height. The proportion between maximum height and depth is default .72: .28. Linespacing alters when a new bodyfont is used or when linespacing is defined explicitly by:

\bfd \setupinterlinespace Now, the interline spacing is larger ... \par

One has to consider the fact that T_EX operates on paragraphs and within a group one has to close the paragraph explicitly with an empty line or par. However, in most cases $ConT_EXT$ will take care of this.

Sometimes a line does not have the maximum height or depth. The next example illustrates this:

It says:

The height and depth of lines differs.

When we put two of these lines above each other we will get:

You can see that the distance is somewhat bigger that the sum of the height and depth of each separate line. This distance is called the baseline distance (\baselineskip) and is in this document 13.8292pt. If we add some extra height to the line we see this:

To prevent the lines from touching T_EX adds a \lineskip, in our example 1.0pt. In a similar way T_EX is taking care of the first line of a page to have at least a height of \topskip (here 12.0pt plus 60.0pt).

Linespacing is set up by:

```
\setupinterlinespace [.*.]

OPTIONAL

* reset small medium auto big on off
```

Linespacing adapts to the size of the actual bodyfont automatically. This means that the user can leave this command untouched, unless a different linespacing is wanted. Instead of a factor one of the predetermined values small (1.0), medium (1.25) or big (1.5) can be given. Below an example is given of a text with a linespacing of 1.25: \setupinterlinespace[medium].

Whenever it comes to my mind that "everything that comes in quantities, will somehow survive", I also got the feeling that in a few hundred years people will draw the saddening conclusion that all those top—ten hits produced by computers represent the summum of todays musical and instrumental abilities. Isn't it true that archeologists can spend a lifetime on speculating about some old coins from the first century? On the other hand, the mere fact that one can have success with this type of non—music success of some top—hit musicians demonstrates both the listeners inability to rate the product and the lack of self criticism of the performers. In principle the future archeologist will therefore draw the right conclusion.

When you make a fontswitch the linespacing is adapted when you give the command \setupinterlinespace without any setup parameters and also when you add the key reset, for example

\setupinterlinespace[reset,medium]

The text below is typeset in the fontsize \tfa, using the following input:

```
\start \tfa \setupinterlinespace
In books meant for children we often find
a somewhat ... when needed. \par \stop
```

In this example the $\protect\operatorname{par}$ is necessary because otherwise $\protect\operatorname{TEX}$ will have forgotten the linespacing before the paragraph is finished (in that case, the paragraph is ended by the empty line after the $\protect\operatorname{stop}$).

In books meant for children we often find a somewhat bigger typeface, for instance because we are convinced that this enables them to read the book themselves. On the other hand, I can also imagine that it is a cheap way to increase the number of pages. Unfortunately scaling up will also uncover the lack of quality of the typesetting used and/or the lack of typographic knowledge of the user of such a system. The interline space sometimes differs on a line by line basis, and depends on the <code>height</code> of the current line. Therefore, when changing the style, something that

should only be done on purpose, also change the baseline distance when needed.

Instead of a keyword, one can pass a key-value pair to define the characteristics of a line.

```
\setupinterlinespace [..,*=.,..]

* height = NUMBER
  depth = NUMBER
  line = DIMENSION
  top = NUMBER
  bottom = NUMBER
```

The default settings are:

```
\setupinterlinespace
[height=.72,
  depth=.28,
  top=1.0,
  bottom=0.4,
  line=2.8ex]
```

The height and depth determine the ratio between the height and depth of a line. The base-line distance is set to 2.8ex. The parameters top and bottom specify the relation between the bodyfont size and the height of the first line and the depth of the last line on a page. The last two quantities are related to TEX's \topskip and \maxdepth.

We will see later that instead of setting the spacing at the document level, i.e. for each font, you can set the spacing per body font environment:

```
\setupbodyfontenvironment
[modern] [12pt]
[interlinespace=14pt]
```

1.5 Emphasize

Within most macropackages the command \em is available. This command behaves like a chameleon which means that it will adapt to the actual typeface. In ConTeXt \em has the following characteristics:

- a switch to *slanted* or *italic* is possible
- a switch within \bf results in *bold slanted* or *bold italic* (when available)
- a so called *italic correction* is performed automatically (\/)

The bold italic or bold slanted characters are supported only when \bs and \bi are available.

```
The mnemonic {\em em} means {\em emphasis}. {\em The mnemonic {\em em} means {\em emphasis}.} {\em \bf The mnemonic {\em em} means {\em emphasis}.} {\em \bf The mnemonic {\em em} {\em emphasis}.}
```

Emphasize 1

```
{\it The mnemonic em {\em means \bf emphasis}.} {\sl The mnemonic em {\em means \bf emphasis}.}
```

This results in:

The mnemonic *em* means *emphasis*.

The mnemonic em means emphasis.

The mnemonic em means emphasis.

The mnemonic em emphasis.

The mnemonic em means **emphasis**.

The mnemonic em means **emphasis**.

The advantage of the use of \em over \it and/or \sl is that consistent typesetting is enforced.

By default emphasis is set at *slanted*, but in this text it is set at *italic*. This setting is made via \setupbodyfontenvironment, see section 1.7.4 for more details:

```
\setupbodyfontenvironment
  [default]
  [em=italic]
```

1.6 Capitals

Words and abbreviations can be typeset in capitals. Both small and big characters are converted into capitals. When \cap is used to typeset a capital the size is that of an \tx. When you switch to slanted (\s1), bold (\bf), etc. the capital letter will also change. Since \cap has a specific meaning in math mode, the formal implementation is called \smallcapped. However in text mode one can use \cap.

```
\cap {.*.}

* TEXT

\Cap {.*.}

* TEXT

\CAP {.*.}

* TEXT

\Caps {...*...}

* WORD
```

The first command converts all letters to a capital. You are advised not to type capital letters in your source file because real small caps distinguishes between small and big letters.

1 Capitals

Capitals for \c qUK $\$ are \c and capitals for \c quantum about capitals in \c $\$ 4Y2K $\$.

this results in:

Capitals for UK are OK and capitals for USA are okay. But what about capitals in Y2K.

A \cap within a \cap will not lead to any problems:

\cap {People that have gathered their \cap {capital} at the cost of other people are not seldom \nocap {decapitated} in revolutionary times.} or:

PEOPLE THAT HAVE GATHERED THEIR CAPITAL AT THE COST OF OTHER PEOPLE ARE NOT SELDOM decapitated IN REVOLUTIONARY TIMES.

In this example you can see that \cap can be temporarily revoked by \nocap.

```
\nocap {.*.}
* TEXT
```

The command \Cap changes the first character of a word into a capital and \CAP changes letters that are preceded by \\ into capital letters. With \Caps you can change the first character of several words into a capital letter.

```
\setupcapitals [.., ** ...]

* title = yes no
sc = yes no
```

With this command the capital mechanism can be set up. The key sc=yes switches to real Small Caps. The key title determines whether capitals in titles are changed.

Next to the former \cap-commands there are also:

```
\Word {.*.}
* WORD
```

and

```
\Words {...*...}
* WORD
```

These commands switch the first characters of a word or words into capitals. All characters in a word are changed with:

Capitals 1

```
\WORD {.*.}
* WORD
```

Let's end this section with real small capitals. When these are available the real small caps \sc are preferred over the pseudo-capital in abbreviations and logos.

In a manual on $TeX\$ and $Con\TeX$ t there is always the question whether to type $cap{TeX}$ and $cap{Con\TeX}$ t} or $cap{TeX}$ and $cap{Con\TeX}$ t}. Both are defined as a logo in the style definition so we type $cap{TEX}$ and $cop{TEX}$, which come out as $cop{TEX}$ and $cop{TEX}$.

Results in:

In a manual on T_EX and $ConT_EXT$ or T_EX and $ConT_EXT$ or T_EX and $ConT_EXT$. Both are defined as a logo in the style definition so we type \TEX and \CONTEXT, which come out as T_EX and $ConT_EXT$.

It is always possible to typeset text in small capitals. However, realize that lower case characters discriminate more and make for an easier read.

An important difference between \cap and \sc is that the last command is used for a specific designed font type. The command \cap on the other hand adapts itself to the actual typeface: *KAP*, *KAP*, *KAP*, etc.

Some typesetting packages stretch words (inter character spacing) to reach an acceptable alignment. In ConTeXt this not supported. On purpose! Words in titles can be stretched by:

```
\stretched {.*.}
* WORD
```

```
\hbox to \hsize {\stretched{there\\is\\much\\stretch\\in ...}} \hbox to 20em {\stretched{... and\\here\\somewhat\\less}}
```

With \setminus you can enforce a space ({} is also allowed).

```
there is much stretch in ... and here somewhat less
```

These typographically non permitted actions are only allowed in heads. The macros that take care of stretching do this by processing the text character by character.

This chapter will not go into the details of underlining because using underlining for typographical purposes is a bad practice. Instead, the commands related to under- and overlining are discussed in section ?? ("??").

1.7 Selecting bodyfonts

The bodyfont (main font), font style and size is set up with:

```
\setupbodyfont [...,*...]

* IDENTIFIER serif regular roman sans support sansserif mono type teletype
handwritten calligraphic 5pt ... 12pt
```

In a running text a temporary font switch is done with the command:

```
\switchtobodyfont [...,*...]

* 5pt ... 12pt small big
```

This command doesn't change the bodyfont in headers and footers. With small and big you switch to a smaller or larger font.

In most cases, the command \setupbodyfont is only used once: in the style definition, and font switching inside the document is done with \switchtobodyfont. Don't confuse these two because that may lead to some rather strange but legitimate effects.

1.7.1 Body font sizes

Body font sizes actually consist of two components. Of course if you specify a size it directly specifies the size at which the main font is loaded, but a number of indirect parameters have to taken care of as well. Think of things like the font size used in headers, footnotes, suband superscripts, as well as the interline space and a few others.

This is why in ConTeXt there is the concept of a *body font environment* (expressed as a dimension), and that is what you pass as an argument to \setupbodyfont or \switchtobodyfont. The definitions as presented above use the indication 5pt ... 12pt for the body font environment, but actually any dimension is acceptable.

The most frequently used sizes are predefined as body font environments: 4pt ... 12pt, 14.4pt, and 17.3pt. But when you use a different, not-yet-defined size specification —for example for a titlepage— ConTeXt will define a body font environment for that size automatically. While doing so, ConTeXt normally works with a precision of 1 decimal to prevent unnecessary loading of fontsizes with only small size differences.

Be warned that in this case, the results may be a less than ideal. The reason is that ConTeXt not just has to load the actual font, but it also has to guess at the various other settings like the relative font sizes and the interline space. It does so by using the values from the nearest smaller body font environment is that is already defined.

You can extend the list of predefined body font environments and even alter the precision in body font matching. See the section 1.7.4 for detailed information about how to tweak or define your own body font sizes.

To end this section, the example below demonstrates how the interline space is adapted automatically, when changing the size of the bodyfont. Consider this input:

```
{\switchtobodyfont[14.4pt] with these commands \par} {\switchtobodyfont[12pt] for font switching \par} {\switchtobodyfont[10pt] it is possible to \par}
```

```
{\switchtobodyfont[8pt] produce an eyetest: \par} {\switchtobodyfont[6pt] a x c e u i w m q p \par}
```

The actual ConTeXt behaviour is shown below on the left. On the right you can see what would have happened if the interline space were not automatically adapted.

with these commands for font switching it is possible to produce an eyetest: axceuiwmqp with these commands for font switching it is possible to produce an eyetest: axceuiwmqp

1.7.2 Body font identifiers

In the definition block of setupbodyfont there was a list of words given besides the special marker IDENTIFIER. These words are the symbolic ConTEXT names for the font styles that we ran into earlier, with a few aliases so that you do not have to worry about the actual naming convention used. The symbolic names are mapped to two-letter internal style abbreviations that are used internally, see table 1.2 for an overview.

Although the macro syntax does not say so, you can use two-letter internal style abbreviations (ss, rm) as well as the longer names, if you prefer.

We have seen already that there are other and easier ways to switch the font style, so if \setup-bodyfont could only be used for this purpose it would not be all that useful. But luckily there is more: the optional IDENTIFIER can be a 'body font name' (aka 'typeface'). Such names have to be predefined, perhaps in a font support file, or simply on earlier lines in the style definition.

A 'typeface' is a symbolic name that links a single font style to actual font families. Such symbolic names are typically grouped together in a definition block that sets up values that link the four styles \rm, \ss, \tt and \mm to fonts in a 'font collection', and such definition blocks are called 'typescripts'.

ConText expects you to define your own font setups, but there are quite a few examples predefined in various typescript files. Not all of those are perpetually loaded, so you usually have to execute a typescript explicitly to get the typeface names predefined. To this end, typescripts themselves also have names.

Executing a typescript is done by \usetypescript. We will get back to \usetypescript later because it is in fact a very flexible command, but let's discuss simple usage first.

```
\usetypescript [.1.] [.2.]
OPTIONAL

1 IDENTIFIER

2 IDENTIFIER
```

A typical input sequence for selecting the predefined 'palatino' set of typefaces in MkII will look like this:

```
\usetypescript[palatino][ec]
\setupbodyfont[palatino,12pt]
```

In this example the typescript named palatino is asked for in the ec font encoding, and that defines a set of typefaces under the name palatino. These are then used by \setupbodyfont and eventually this makes PDFTEX load the free Type 1 font URW Palladio in the correct encoding. URW Palladio is a font that looks a lot like the commercial font Linotype Palatino by Hermann Zapf, which explains the name of the typescript and typefaces.

Font encodings will be handled fully in the section 1.13. For now, please take for granted the fact that PDFTEX needs a second argument to \usetypescript that specifies an encoding name, and that there is a fixed set of acceptable names that depends on the typescript that is being requested.

In XaTeX and MkIV the situation is a little bit different because fonts are reencoded to match Unicode whenever that is possible. That in turn means that XaTeX and MkIV prefer to use OpenType fonts over Type 1 fonts, so different typescript definitions are used behind the scenes, and the second argument to \usetypescript becomes optional.

For example,

\usetypescript[palatino]
\setupbodyfont[palatino,12pt]

will make XaTeX and LuaTeX load the OpenType font Pagella. This is a free font from the TeX Gyre project, that also looks just like the commercial font Linotype Palatino. You may as well leave the second argument in place: while it will always be ignored by LuaTeX, XaTeX will actually use that encoding if the typescript uses Type 1 fonts instead of the more modern OpenType or TrueType font formats.

All predefined typescripts attach meaning to (at least) the three basic text font styles, so you can e.g. do this:

```
\usetypescript[times][ec]
\setupbodyfont[times,sans,12pt]
```

and end up using the OpenType font TEX Gyre Heros or the Type 1 font URW Nimbus Sans L. Both fonts are very similar in appearance to Linotype Helvetica, by the way.

The typescripts that come with the ConTeXt distribution are placed in source files that have names that start with type-. Some of these files are automatically loaded when needed, but most have to be loaded explicitly. There is a list in table 1.6

Some of the internal building blocks for typescripts are themselves located in yet other files (font size and font map file information, for example). Normally, when ConTeXt has to load typescript information from files, it will try to save memory by only executing the typescript it needs at that moment and discarding all other information. If you have enough memory at your disposal, you can speed up typescript use considerably by adding

\preloadtypescripts

in your preamble or your cont-usr.tex. This will make ConTEXT store all the typescript information in internal token registers the first (and therefore only) time it loads the actual files.

Explicit loading one of those files is done via the macro \usetypescriptfile.

The predefined typescripts, the typefaces they define, the files they are contained in inside the ConTeXt distribution, and the encodings they support in MkII mode are listed in table 1.7.

| File | Loaded by PDFTEX | Loaded by X _H T _E X | Loaded by MĸIV | Description |
|----------|---------------------|--|-------------------|--|
| type-akb | no | no | no | PostScript fonts using psnfss names (Type 1) |
| type-buy | no | no | no | Various commercial fonts (Type 1) |
| type-cbg | no | no | no | Greek free fonts (Type 1) |
| type-cow | no | no | no | The ConTeXt cow font (Type 1) |
| type-exp | no | no | no | Commercial Zapf fonts (OpenType) |
| type-fsf | no | no | no | Commercial Fontsite 500 fonts (Type 1) |
| type-ghz | no | no | no | Commercial Zapf fonts (Type 1) |
| type-gyr | no | no | no | The T _E X Gyre project fonts (Type 1) |
| type-hgz | no | no | no | Commercial Zapf fonts (OpenType) |
| type-msw | no | no | no | Fonts that come with Microsoft Windows (Type 1) |
| type-omg | no | no | no | Omega free fonts (Type 1) |
| type-one | yes | no | no | Various free fonts (Type 1) |
| type-otf | no | yes | yes | Various free fonts (OpenType) |
| type-xtx | no | yes | no | Fonts that come with MacOSX (OpenType) |

Table 1.6 The typescript source files that are part of ConTEXT.

In the following section there is a table (1.8) that explains for each typescript what font set it attaches to each of the font styles.

```
\usetypescriptfile [.*.]
* IDENTIFIER
```

For example, the following

```
\usetypescriptfile[type-buy]
\usetypescript[lucida][texnansi]
\setupbodyfont[lucida,12pt]
```

will make PDFTEX use the Lucida Bright font family. Because this is a commercial font, this only works correctly if you have actually bought and installed the fonts. This uses the texnansi encoding because that is the preferred encoding of the actual fonts.

This is a good moment to explain a little trick: because the various type-xxx files define the building blocks for typescripts as well as the actual typescripts, it is sometimes possible to alter the effect of a typescript by loading an extra typescript file. For example,

```
\usetypescriptfile[type-gyr]
\usetypescript[palatino][ec]
\setupbodyfont[palatino,12pt]
```

will result in PDFTEX using the Type 1 font Pagella from the TEX Gyre project instead of the older and less complete URW Palladio, because the definition of the building blocks for the palatino typescript that is in the type-gyr file overwrites the preloaded definition from the type-one file.

Two of the files in the ConTeXt distribution exist precisely for this reason:

```
type-gyr.tex
  maps the typical PostScript font names for the free URW fonts to the TEX Gyre set;
type-akb.tex
```

| Typescript OmegaLGC | Typeface omlgc | File type-omg | Encodings (unspecified) |

| | | , , , , , | , ,1 , , |

Table 1.7 The typescripts. Typescripts that use commercial fonts are typeset in bold.

maps the same names to the commercial Adobe fonts.

For the defintions in the second file to work, you also need to execute an extra typescript:

```
\usetypescriptfile [type-akb] \usetypescript [adobekb] [ec]
```

\usetypescript [palatino] [ec]
\setupbodyfont[palatino,12pt]

1.7.3 Typeface definitions

Defining a typeface goes like this:

```
\starttypescript [palatino] [texnansi,ec,qx,t5,default]
```

\definetypeface[palatino] [rm] [serif][palatino] [default]

```
\definetypeface[palatino] [ss] [sans] [modern] [default] [rscale=1.075] \definetypeface[palatino] [tt] [mono] [modern] [default] [rscale=1.075] \definetypeface[palatino] [mm] [math] [palatino] [default]
```

\stoptypescript

This defines a typescript named palatino in five different encodings. When this typescript is executed via \usetypescript, it will define four typefaces, one of each of the four basic styles rm, ss, tt, and mm.

```
\definetypeface [.1.] [.2.] [.3.] [.4.] [.5.] [.6.]
OPTIONAL OPTIONAL

1  TEXT
2  rm ss tt mm hw cg
3  IDENTIFIER
4  IDENTIFIER
5  IDENTIFIER
6  features = IDENTIFIER
    rscale = NUMBER
    encoding = IDENTIFIER
    text = IDENTIFIER
```

The third and fourth arguments to \definetypeface are pointers to already declared font sets, these are defined elsewhere. Table 1.8 gives the full list of predefined typescripts (the first argument of \starttypescript) and font sets that are attached to the styles (the third and fourth argument of each \definetypeface).

The names in the third argument (like serif and sans) do not have the same meaning as the names used in \setupbodyfont. Inside \setupbodyfont, they were keywords that were internally remapped to one of the two-letter internal styles. Inside \definetypeface, they are nothing more than convenience names that are attached to a group of fonts by the person that wrote the font definition. They only reflect a grouping that the person believed that could be a single font style. Oftentimes, these names are identical to the official style keywords, just as the typescript and typeface names are often the same, but there can be (and are) different names altogether.

How to define your own font sets will be explained in the next chapter, but there are quite a few predefined font sets that come with ConTeXt; these are all listed in the four tables 1.9, 1.10, 1.11, and 1.12.

For everything to work properly in M κ II, the predefined font sets also have to have an encoding attached, you can look those up in the relevant tables as well.

The fifth argument to \definetypeface specifies specific font size setups (if any), these will be covered in section ?? in the next chapter. Almost always, specifying default will suffice.

The optional sixth argument is used for tweaking font settings like the specification of font features or adjusting parameters. In this case, the two modern font sets are loaded with a small magnification, this evens out the visual heights of the font styles.

| Typescript OmegaLGC | Style rm omega | Style ss | Style tt omega | Style mm |

| times | times | helvetica | modern | times |

Table 1.8 The typescripts.

Unless stated otherwise, style **rm** uses a group named serif, style **ss** uses sans, style **tt** uses mono, and style **mm** uses math. A single dash in a cell means that the typescript does not define that style, you should refrain from using the style. The lucida, lucidabfm, and lucidaboldmath typescripts also define **hw** and **cg** as 'lucida handwring' and 'lucida calligraphy'. The modern-base typescript switches back to computer-modern for a few legacy encodings: t2a, t2b, and t2c.

There are four possible keys in the sixth argument:

| key | default value | explanation |
|------------------|------------------|---|
| rscale | 1 | a scaling factor for this typescript relative to the selected body font size |
| encoding | \defaultencoding | the encoding for the typeface, normally inherited from the typescript automatically |
| features text | | this applies a predefined font feature set (see section 1.8) sets up the forced math text style |

A note for the lazy: if the sixth argument is not given and the fifth argument happens to be default, then the fifth argument can be omitted as well.

In table 1.12 you will see three very special items: Xserif, Xsans and Xmono. These belong to a special XTFX-only trick called 'wildcard typescripts'.

X₃T_EX offers some nice features in terms of automatically finding related fonts in a family, namely the italic, bold, and bolditalic alternatives. To take advantage of that, there's a set of wildcard typescripts that take an arbitrary Macintosh font name as input, and provide as many of the alternatives it can find. To set these typescripts (and the calling conventions) apart from the familiar ones, the typescripts are identified with Xserif, Xsans, and Xmono.

To call the typescripts, it's most convenient to define a typeface that uses these features. The named font slot should contain the display name of the Regular alternative (not the family name) of the font in question. For example, you could have the following mix:

```
\starttypescript[myface]
\definetypeface[myface][rm][Xserif][Baskerville] [default]
\definetypeface[myface][tt][Xmono] [Courier] [default][rscale=.87]
\definetypeface[myface][ss][Xsans] [Optima Regular][default]
\stoptypescript
```

As you can see, you can activate relative scaling of face sizes. The above definitions look very much like any other typeface definition, except that the serif/sans/mono identifier is preceded with X, and that there is no underlying "Optima Regular" defined anywhere. Those missing bits of the definitions are handled by typescript and XATEX magic.

1.7.4 Body font environments

Earlier we have seen that within a font family there are different font sizes. The relations between these sizes are defined by *body font environments*.

For all regular font sizes, environments are predefined that fulfill their purpose adequately. However when you want to do some extra defining yourself there is:

The first argument is optional, and specifier the typeface identifier that this particular body font environment setup is for. It defaults to the current typeface.

| Identifier | file | Encodings | Supported styles |
|----------------------------|----------------------|--|--|

Table 1.11 The predefined body font identifiers for free Unicode (Opentype) fonts

The second argument is the size of the body font environment that is being defined. This argument is not really optional, the macro syntax description is a little misleading.

The third argument once again is optional, and contains the actual settings as key-value pairs. If it is missing, defaults will be guessed at by ConTeXt itself.

Table 1.12 The predefined body font identifiers for commercial Unicode (Opentype) fonts

```
scriptscript Math scriptscript size
```

 ${\tt x}$ The size used for the ${\tt tfx}$ etc. commands ${\tt xx}$ The size used for the ${\tt tfxx}$ command

big The 'larger' font size small The 'smaller' font size

interlinespace Distance between lines in a paragraph, can be ignored because a reasonable

default is always set up

em The style to use for emphasis (default is slanted)

So, when you want to have a somewhat bigger fontsize for just a few words (e.g. for a book title) you can type:

```
\definebodyfontenvironment [24pt] \switchtobodyfont[24pt]
```

but longer stretches of text, you will need to set up most of the values, using something like this

```
\definebodyfontenvironment
  [22pt]
  [ text=22pt,
```

To tweak already defined sizes, there is an accompagnying setup command with the same parameter conventions:

```
\setupbodyfontenvironment [.1.] [.2.] [.., 3..]

OPTIONAL OPTIONAL

1 inherits from \definebodyfontenvironment

2 inherits from \definebodyfontenvironment

3 inherits from \definebodyfontenvironment
```

1.8 Font feature sets

As mentioned already, some fonts contain extra information besides the actual glyph shapes. In traditional TEX fonts, the extra information is roughly limited to kerning pairs and ligature information, and both of these 'features' are automatically applied to the text that is being typeset. In the odd case where one of the two needs to be suppressed, a little bit of macro trickery can do the job without too many complicating factors.

But with the new OpenType font format that is used by XaTeX and LuaTeX, the list of possible features is increased enormously. OpenType fonts have not just kerning information and ligature information, but there can also be other features like optional oldstyle figures, caps and smallcaps glyphs, decorative swashes, etc. all inside a single font file.

Not only that, but some of these features are not even supposed to be active all the time. Certain features should only be activated if the user asks for it, other features depend on the script and language that is in use for the text that is being typeset.

This is a big step forward in that there are now far fewer fonts needed to achieve the same level of quality than before, all that extra font information also poses a big challenge for macro writers. And add to that the fact that at the core, the two engines (X_HT_EX and LuaT_EX) handle OpenType fonts completely different from each other.

ConTEXT has a new subsystem called 'font features' to create order in this forest of features. The most important command is \definefontfeature. This command can be used to group various font features under a single symbolic name, that can then be used as e.g. the argument to the features key of \definetypeface.

Font feature sets 1

```
\definefontfeature [.1.] [.2.] [.3.]

1  TEXT

2  IDENTIFIER

3  compose = no yes
  mode = node base
  tlig = no yes
  trep = no yes
  script = IDENTIFIER
  language = IDENTIFIER
  ..tag. = no yes
```

\definefontfeature

```
[default-base]
```

```
[script=latn,language=dflt,liga=yes,kern=yes,tlig=yes,trep=yes]
```

As you can probably guess, the first argument is the symbolic name that is being defined. The second argument is a mix of a-hoc settings and OpenType font features.

| compose | Use fallback composition in MkIV (see section ??) |
|------------|---|
| protrusion | Character protrusion in MkIV (see section 1.12) |
| expansion | Character expansion in MkIV (see section 1.12) |

script An OpenType script identifier

language An OpenType script language identifier

tlig A virtual feature for legacy (TEX-style) automatic ligatures (for compatibility,

there is an alias for this key called texligatures)

trep A virtual feature for legacy (T_FX-style) automatic ligatures (for compatibility,

there is an alias for this key called texquotes) (only works in $M\kappa IV$)

mode Processing mode for MkIV. node and base allowed, base is default

<tag> Any OpenType feature tag is acceptable, but in MkIV only a 'known' subset ac-

tually has any effect, and then only in node mode. This list is given in table 1.13. In $X_{\overline{1}}T_{\overline{1}}X$, processing depends on the internal subengine that is used by $X_{\overline{1}}T_{\overline{1}}X$,

and that is outside of ConTEXT's control.

A few fontfeatures are predefined by context:

```
default liga=yes,kern=yes,tlig=yes,trep=yes
smallcaps liga=yes,kern=yes,tlig=yes,trep=yes,smcp=yes
oldstyle liga=yes,kern=yes,tlig=yes,trep=yes,onum=yes
```

At the moment, smallcaps and oldstyle only work in X $_{\overline{A}}$ TeX (in M $_{\kappa}$ IV, it would need an extra mode=node pair).

1.9 Displaying the current font setup

With the command \showbodyfont an overview is generated of the available characters, and an overview of the different fontsizes within a family can be summoned with \showbodyfontenvironment.

Table 1.13 The OpenType features that are understood by MκIV in mode=node processing mode

```
\showbodyfont [...*,...]

* inherits from \setupbodyfont

\showbodyfontenvironment [...*,...]

OPTIONAL

* inherits from \setupbodyfont
```

Specifiying actual IDENTIFIERs to these commands is currently unreliable because they internally are still counting on an older system of body font definitions, but you can safely use a size argument to get the information for the current font set.

Below an example of the possible output is shown, for \showbodyfont [12pt]

| | [palatino] [12pt] \mr: A | | | | | | | | | | | : Ag | |
|-----|--------------------------|-----|-----|-----|-----|-----|-----|------|-------|------|------|------|------|
| | \tf | \sc | \sl | \it | \bf | \bs | \bi | \tfx | \tfxx | \tfa | \tfb | \tfc | \tfd |
| \rm | Ag | AG | Ag | Ag | Ag | Ag | Ag | Ag | Ag | Ag | Ag | Ag | Ag |
| \ss | Ag | Ag | Ag | Ag | Ag | Ag | Ag | Ag | Ag | Ag | Ag | Ag | Ag |
| \tt | Ag | AG | Ag | Ag | Ag | Ag | Ag | Ag | Ag | Ag | Ag | Ag | Ag |

And the output of \showbodyfontenvironment[12pt] is:

| [palatino] [12pt] | | | | | | | |
|-------------------|--------|--------------|--------|--------|--------|--------|----------------|
| text | script | scriptscript | х | xx | small | big | interlinespace |
| 20.7pt | 14.4pt | 12pt | 17.3pt | 14.4pt | 17.3pt | 20.7pt | not set |
| 17.3pt | 12.1pt | 8.6pt | 13.8pt | 10.3pt | 13.8pt | 20.7pt | not set |
| 14.4pt | 10pt | 7.2pt | 11.5pt | 8.6pt | 11.5pt | 17.2pt | not set |
| 12pt | 8.3pt | 6pt | 9.6pt | 7.2pt | 9.6pt | 14.3pt | not set |

1.10 Math fonts

There are only a few font families in existance that can handle math properly because such fonts have to carry a complete set of characters and symbols for mathematical typesetting. Among these, the Computer Modern Roman distinguishes itself by its many design sizes; that really pays off when typesetting complicated math formulas.

Many TEX users have chosen TEX for its superb math typesetting.

This chapter will not go into any details but in math mode, the central concept is the *math family* (not to be confused with the *font families* discussed earlier). There are math families for \bf, \it, etc. as well as for the special math symbols. Within each family, there are always exactly three member fonts: text, script and scriptscript, or a normal, smaller and smallest font.

1 Math fonts

The normal font size is used for running text and the smaller ones for sub and superscripts. The next example will show what the members of a math family can do.

```
\t x^2+\b x^2+
```

When this is typeset you see this:

$$x^{2} + x^{2} + x^{2} + x^{2} + x^{2} + x^{2} = 6x^{2}$$

$$x^{2} + x^{2} + x^{2} + x^{2} + x^{2} + x^{2} = 6x^{2}$$

$$x^{2} + x^{2} + x^{2} + x^{2} + x^{2} + x^{2} = 6x^{2}$$

$$x^{2} + x^{2} + x^{2} + x^{2} + x^{2} + x^{2} = 6x^{2}$$

As you can see, the alphabetic characters adapt to the selected font family but the symbols are all typeset in the same font regardless. Technically this means that the symbols are set in the fixed font family 0 whereas the alphabetic characters are typeset using variable family numbers.

Typeseting math formulas can also be done somewhat differently, as we will see in the next example.

```
$\tf\mf x^2 + x^2 + x^2 + x^2 + x^2 + x^2 = 6x^2$
$\bf\mf x^2 + x^2 + x^2 + x^2 + x^2 + x^2 = 6x^2$
$\sl\mf x^2 + x^2 + x^2 + x^2 + x^2 + x^2 = 6x^2$
$\s\mf x^2 + x^2 + x^2 + x^2 + x^2 + x^2 = 6x^2$
$\t\mf x^2 + x^2 + x^2 + x^2 + x^2 + x^2 = 6x^2$
$\t\mf x^2 + x^2 + x^2 + x^2 + x^2 + x^2 = 6x^2$
$\t\mf x^2 + x^2 + x^2 + x^2 + x^2 + x^2 = 6x^2$
```

A new command is used: \mf, which stands for *math font*. This command takes care of the symbols in such a way that they are also set in the actually selected font, just like the characters.

$$x^{2} + x^{2} + x^{2} + x^{2} + x^{2} + x^{2} = 6x^{2}$$

$$x^{2} + x^{2} + x^{2} + x^{2} + x^{2} + x^{2} = 6x^{2}$$

$$x^{2} + x^{2} + x^{2} + x^{2} + x^{2} + x^{2} = 6x^{2}$$

$$x^{2} + x^{2} + x^{2} + x^{2} + x^{2} + x^{2} = 6x^{2}$$

$$x^{2} + x^{2} + x^{2} + x^{2} + x^{2} + x^{2} = 6x^{2}$$

$$x^{2} + x^{2} + x^{2} + x^{2} + x^{2} + x^{2} = 6x^{2}$$

You should take into account that TEX typesets a formula as a whole. In some cases this means that setups at the end of the formula have an effect that starts already at the beginning of the fomula.

For example, the exact location of \mf is not that important. We also could have typed:

$$h^2 x^2 + x^2 + x^2 + x^2 + x^2 + x^2 = mf 6x^2$$

There is much more to be said about math, but it is better to do that in chapter ??, about math.

1.11 Em and Ex

In specifying dimensions we can distinguish physical units like pt and cm and internal units like em and ex. These last units are related to the actual fontsize. When you use these internal units

Em and Ex 1

in specifying for example horizontal and vertical spacing you don't have to do any recalculating when fonts are switched in the style definition.

Some insight in these units does not hurt. The width of an em is not the with of an em, but that of an — (an em-dash). When this glyph is not available in the font another value is used. Table 1.14 shows some examples. We see that the width of a digit is about .5em. In Computer Modern Roman a digit is excactly half an em wide.

| \tf | \bf | \sl | \tt | \ss | \tfx |
|-----|----------|---------------|-----|----------|----------|
| 12 | 12 | 12 | 12 | 12 | 12 |
| M | M | M | M | M | M |
| | | | | | |
| H | \vdash | $\mid H \mid$ | | \vdash | \vdash |

Table 1.14 The width of an em.

In most cases we use em for specifying width and and ex for height. Table 1.15 shows some examples. We see that the height equals the height of a lowercase x.

| \tf | \bf | \sl | \tt | \ss | \tfx |
|----------|-----------|------------|-----|-----|------|
| <u>x</u> | <u>_x</u> | $\equiv x$ | x | x | _x |

Table 1.15 The height of an ex.

1.12 Font handling

Almost all users of typesetting systems based on TEX do so because of the quality of the output it produces. PDFTEX (and through inheritance LuaTEX as well) contains a few extensions to the typesetting engine that make the output even better than the results achieved by Knuth's original TEX. Although the extensions are made available by PDFTEX, they are not limited to the PDF output, they will work with the DVI backend just as well. And when the extensions are defined but not enabled, then the typeset output is 100% identical to when the feature is not present at all.

Before we go into the details of the actual extensions, let's see what is provided by ConTeXt as the user-level interface. The ConTeXt interface to those new features is through a subsystem called 'font handling', and at the top that subsystem is seamlessly integrated into the normal alignment macros.

For example, assuming the system is set up already to support protrusion, you can simply say \setupalign[hanging]

to turn protrusion on. However, this will only work correctly if a number of special setups have taken place internally. The command \setupalign only toggles a switch, and the required setups have to be done elsewhere.

The list of font handling-related keys for \setupalign is:

hanging turns on character protrusion (see the next section)

nohanging turns off character protrusion

hz turns on font expansion (see section 1.12.2)

nohz turns off font expansion

spacing turns on special spacing rules (see section 1.12.3)

nospacing turns off special spacing

Now, let's move on to how to set up the system for font handling properly. The underlying features of PDFTEX can not *just* be turned on or off, it is possible to tweak the machinery on the font as well as on the individual glyph level. You can define those settings all on your own, but ConTeXT comes with a handy set of predefined values.

1.12.1 Character protrusion

| In the following fake paragraph, you can see a hyphenation point, a secondary sentence, sep- |
|--|
| arated by a comma, and a last sentence, ending with a period. Miraculously, this paragraph |
| fits into lines. Although exaggerated, these lines demonstrate that visually the hyphen and |
| punctuation characters make the margin look ragged. |

| Before computers started to take over the traditional typesetter's job, it was common practice to move hyphens and punctuation into the margin, like in: |
|--|
| |
| |
| |
| |
| |

In this alternative, the margin looks less ragged, and this becomes more noticable once you get aware of this phenomenon.

Sometimes, shifting the characters completely into the margin is too much for the sensitive eye, for instance with a slanted font, where the characters already hang to the right. In such cases, we need to compromise.

Font handling

1

PDFTEX (and LuaTeX, that has inherited this feature) has provisions to move characters into the margin when they end up at the end of a line. Such characters are called protruding characters. PDFTEX takes protruding into account when breaking a paragraph.

We will demonstrate protruding using a quote from Hermann Zapf's article "About microtypography and the *hz*–program" in Electronic Publishing, vol 6 (3), 1993.

Coming back to the use of typefaces in electronic publishing: many of the new typographers receive their knowledge and information about the rules of typography from books, from computer magazines or the instruction manuals which they get with the purchase of a PC or software. There is not so much basic instruction, as of now, as there was in the old days, showing the differences between good and bad typographic design. Many people are just fascinated by their PC's tricks, and think that a widely||praised program, called up on the screen, will make everything automatic from now on.

After TEX has typeset this paragraph (using a specific font size and line width) it may have constructed the following lines.

Coming back to the use of typefaces in electronic publishing: many of the new typographers receive their knowledge and information about the rules of typography from books, from computer magazines or the instruction manuals which they get with the purchase of a PC or software. There is not so much basic instruction, as of now, as there was in the old days, showing the differences between good and bad typographic design. Many people are just fascinated by their PC's tricks, and think that a widely-praised program, called up on the screen, will make everything automatic from now on.

As you can see, the height and depth of the lines depend on the characters, but their width equals what TEX calls \hsize. However, the natural width of the lines may differ from \hsize.

Coming back to the use of typefaces in electronic publishing: many of the new typographers receive their knowledge and information about the rules of typography from books, from computer magazines or the instruction manuals which they get with the purchase of a PC or software. There is not so much basic instruction, as of now, as there was in the old days, showing the differences between good and bad typographic design. Many people are just fascinated by their PC's tricks, and think that a widely-praised program, called up on the screen, will make everything automatic from now on.

Here the inter–word space is fixed to what TEX considers to be a space. This example also demonstrates that TEX does not have spaces, but stretches the white area between words to suit its demands. When breaking lines, TEX's mind is occupied by boxes, glue and penalties, or in more common language: (parts of) words, stretchable white space, and more or less preferred breakpoints.

Coming back to the use of typefaces in electronic publishing: many of the new typographers receive their knowledge and information about the rules of typography from books, from computer magazines or the instruction manuals which they get with the purchase of a PC or software. There is not so much basic instruction, as of now, as there was in the old days, showing the differences between good and bad typographic design. Many people are just fascinated by their PC's tricks, and think that a widely-praised program, called up on the screen, will make everything automatic from now on.

This time we have enabled PDFTEX's protruding mechanism. The characters that stick into the margin are taken into account when breaking the paragraph into lines, but in the final result, they do not count in the width. Here we used an ugly three column layout so that we got a few more hyphens to illustrate the principle, but in the next examples we will stick to two columns.

Coming back to the use of typefaces in electronic publishing: many of the new typographers receive their knowledge and information about the rules of typography from books, from computer magazines or the instruction manuals which they get with the purchase of a PC or software. There is not so much basic instruc-

tion, as of now, as there was in the old days, showing the differences between good and bad typographic design. Many people are just fascinated by their PC's tricks, and think that a widely–praised program, called up on the screen, will make everything automatic from now on.

In this first example the text was typeset in the traditional way. The hyphens and punctuation fit into the margin.

Coming back to the use of typefaces in electronic publishing: many of the new typographers receive their knowledge and information about the rules of typography from books, from computer magazines or the instruction manuals which they get with the purchase of a PC or software. There is not so much basic instruc-

tion, as of now, as there was in the old days, showing the differences between good and bad typographic design. Many people are just fascinated by their PC's tricks, and think that a widely–praised program, called up on the screen, will make everything automatic from now on.

In this example, the protruding machinery is put to work. The hyphens and punctuation may now stick into the margin completely. The next two examples shows what happens when we limit the protruding to 75% and 50% respectively.

Coming back to the use of typefaces in electronic publishing: many of the new typographers receive their knowledge and information about the rules of typography from books, from computer magazines or the instruction manuals which they get with the purchase of a PC or software. There is not so much basic instruc-

tion, as of now, as there was in the old days, showing the differences between good and bad typographic design. Many people are just fascinated by their PC's tricks, and think that a widely-praised program, called up on the screen, will make everything automatic from now on.

Coming back to the use of typefaces in electronic publishing: many of the new typographers receive their knowledge and information about the rules of typography from books, from computer magazines or the instruction manuals which they get with the purchase of a PC or software. There is not so much basic instruc-

tion, as of now, as there was in the old days, showing the differences between good and bad typographic design. Many people are just fascinated by their PC's tricks, and think that a widely–praised program, called up on the screen, will make everything automatic from now on.

Also because of this tight connection with the font itself, the method of setting up the support at the font level is a little different between PDFTEX and MkIV.

IN PDFTEX, setting up the handling takes place in a similar way as encoding, like so:

\definefontsynonym

[myfont] [Serif] [handling=pure]

But you can also specify a handler at a higher level of abstraction:

\setupfontsynonym [Lucida-Bright] [handling=pure]

Or even:

\setupfontsynonym [Serif] [handling=pure]

In MkIV, font handling is merged with font the features (because these already have a low-level connection to the font), so you can set up the font-side of things with the sixth argument of \definetypeface , or by redefining the feature set that is used by the typescript you are using and then (re-)executing the typescript, like so:

\definefontfeature
 [default] [default]
 [protrusion=pure,mode=node,script=latn]
\usetypescript[modern]

So far we have used so-called pure protrusion, this extends the punctuation and hyphenation characters into the margin completely. The settings that Hàn Thế Thành mentions in his thesis for protrusion are available under the names punctuation and alpha:

| vector | protruding character set |
|-------------------|---|
| punctuation | hyphenation and punctuation characters, but using a more subtle approach than pure (characters stick out by specific percentages) |
| alpha extended | the latin alphabet characters the other characters |

The extended category maps the special (latin) characters onto the base 26 ones, and thereby honors the font encoding vector. This mapping vector can be used to enhance other handling vectors with support for accented characters (in most cases á, à, etc. need a treatment similar to a).

TODO: this is vague

Font protruding is turned off automatically in some particular situations, more control over that will be added eventually.

1.12.2 Font expansion

In typesetting the two characters hz are tightly connected to Hermann Zapf and the next couple of pages we will discuss a method for optimizing the look and feel of a paragraph using a mechanism that is inspired on his work. Although official qualified in PDFTEX as font adjusting, we will use the short qualification hz since this is how it is called in the PDFTEX community.

First, here is again the same example text that was used in the previous section, typeset using normal TEX—comptibale font settings:

Coming back to the use of typefaces in electronic publishing: many of the new typographers receive their knowledge and information about the rules of typography from books, from computer magazines or the instruction manuals which they get with the purchase of a PC or software. There is not so much basic instruc-

tion, as of now, as there was in the old days, showing the differences between good and bad typographic design. Many people are just fascinated by their PC's tricks, and think that a widely–praised program, called up on the screen, will make everything automatic from now on.

The Example below shows hz in action. This paragraph is typeset with hz enabled and has a more even spacing than the text above.

Coming back to the use of typefaces in electronic publishing: many of the new typographers receive their knowledge and information about the rules of typography from books, from computer magazines or the instruction manuals which they get with the purchase of a PC or software. There is not so much basic instruc-

tion, as of now, as there was in the old days, showing the differences between good and bad typographic design. Many people are just fascinated by their PC's tricks, and think that a widely–praised program, called up on the screen, will make everything automatic from now on.

The average reader will not notice the trick, but those sensitive to character shapes will see that some glyphs are widened slightly and others are narrowed slightly. Ideally the programs that built the glyph should be defined in such a way that this goes unnoticed, but in practice glyph programs are not that clever and so a brute force horizontal scaling is applied. As long as the used percentage is small, the distortion will go unnoticed and the paragraph will look slightly better because the whitespace distribution is more even.

1.12.3 Other font handlings

In addition to the two handlings documented in the previous pararaphs (protruding and hz), ConTeXt also provides the noligs handling (handy when one processes xml), flexspacing and prespacing (meant for languages like French that need spacing around for instance : and ;). These handlings are somewhat experimental.

1.12.4 Defining font handlings

At the lowest level, the font handling definitions look like this (here showing the default punctuation handling):

```
\startfonthandling[punctuation]
\defineprotrudefactor, 0 .7
\defineprotrudefactor. 0 .7
```

\defineprotrudefactor: 0 .5 \defineprotrudefactor; 0 .5

.

\stopfonthandling

Equally valid are definitions like:

\defineprotrudefactor hyphen 0 .7

Any character can protrude:

\defineprotrudefactor A .05 .05

For convenience we let composed characters inherit the values from their parents.

```
\inheritprotrudefactor Acircumflex A
```

The two fractional arguments are a proportion of the width of the glyph, one for the left shift and one for the right shift. There are a few more vectors defined, like defalph for characters, where only very small shifts are applied.

A combination of such vectors is then packaged to become a font handler using the following command:

```
\definefonthandling [normal] [punctuation,alpha]
```

and such definitions are then loaded with the \usehandling command. You could for instance load the default definitions with:

```
\usehandling[def]
```

But since this handling vector is already preloaded in ConTeXt (just like all the others that were mentioned so far), you normally don't have to provide this command yourself.

1

As already mentioned, the amount of protruding depends on the shape, which is why different values may be needed for slanted or bold shapes. One way of using the same vector for different shapes, is changing the strength of the protruding:

\definefonthandling [slanted] [punctuation] [right=1.5]

Here, because a slanted glyph already sticks into the margin, we limit protruding to punctuation. You may expect more (probably incompatible) fine tuning in the future.

1.13 Encodings and mappings

This paragraph only applies to PDFTEX. If you are exclusively using XHTEX or MkIV, you can safely ignore the following text.

Not every language uses the (western) latin alphabet. Although in most languages the basic 26 characters are somehow used, they can be combined with a broad range of accents placed in any place.

In order to get a character representation, also called glyph, in the resulting output, you have to encode it in the input. This is no problem for a..z, but other characters are accessed by name, for instance \eacute. The glyph \(\epsilon\) can be present in the font but when it's not there, TEX has to compose the character from a letter e and an accent \(\cdot\).

In practice this means that the meaning of \eacute depends on the font and font encoding used. There are many such encodings, each suited for a subset of languages.

| encoding | usage | status |
|----------|---|----------|
| 8r | a (strange) mixture of encodings | useless |
| default | the 7 bit ASCII encoding as used by plain TeX | obsolete |
| ec | the prefered encoding of T _F X distributions | okay |
| greek | an encoding for modern greek | okay |
| qx | an encoding that covers most eastern european languages | okay |
| t2a | a cyrillic TEX font encoding | ? |
| t2b | another cyrillic T _E X font encoding | ? |
| t2c | another another cyrillic T _E X font encoding | ? |
| t5 | an encoding dedicated to vietnamese (many (double) accents) | okay |
| texnansi | a combination of TEX and Adobe standard encoding | okay |

These encodings are font related as is demonstrated in figure 1.1, 1.2, 1.3, and 1.4. Here we used the \showfont command.

The situation is even more complicated than it looks, since the font may be virtual, that is, built from several fonts.

The advantage of using specific encodings is that you can let TEX hyphenate words in the appropriate way. The hyphenation patterns are applied to the internal data structures that represent the sequence of glyphs. In spite of what you may expect, they are font–dependent! Even more confusing: they not only depend on the font encoding, but also on the mapping from lower to uppercase characters, or more precise, on the existence of such a mapping.

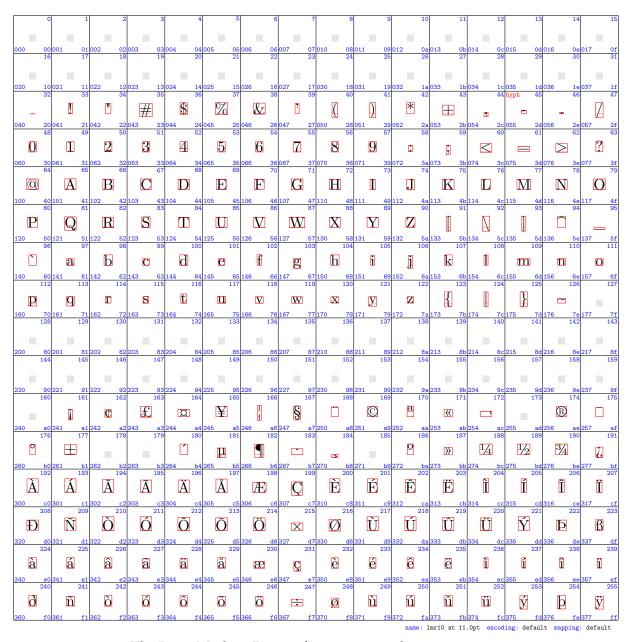

Figure 1.1 The Latin Modern Roman font in ec encoding.

Unless you want to play with these encodings and mappings, in most cases you can forget their details and rely on what other TEX experts tell you to do. Normally switching from one to another encoding and/or mapping takes place with the change in fonts or when some special output encoding is needed, for instance in PDF annotations and/or unicode vectors that enable searching in documents. So, to summarize this: encodings and mappings depend on the fonts used as well have consequences for the language specific hyphenation patterns. Fortunately ConTEXT handles this for you automatically.

If you want to know to what extent a font is complete and characters need to be composed on the fly, you can typeset a a couple of tables. The (current) composition is shown by \showaccents:

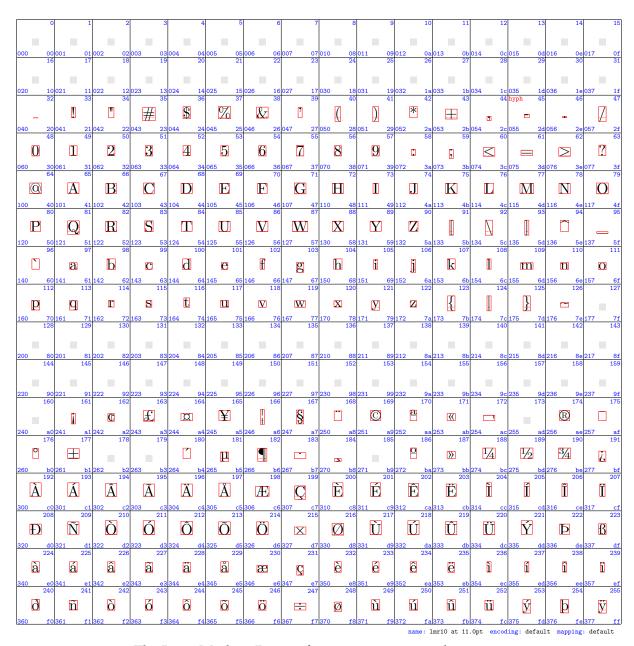

Figure 1.2 The Latin Modern Roman font in texnansi encoding.

```
